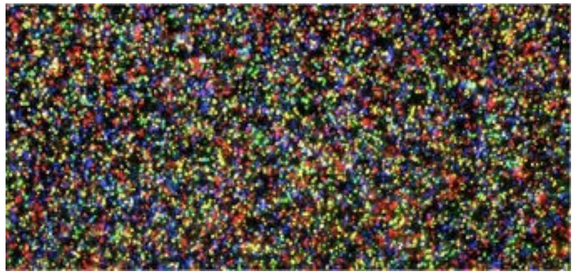
Onkologie im Wandel der Zeit

„… und an der Brust sahen wir häufig Tumoren, die der Gestalt eines Krebses sehr ähnlich waren. So wie die Beine des Tieres an beiden Seiten des Körpers liegen, so verlassen die Venen den Tumor, der seiner Form nach dem Krebskörper gleicht.“

Galenos von Pergamon 2. Jh. n. Chr.

Next-Generation-Sequencing



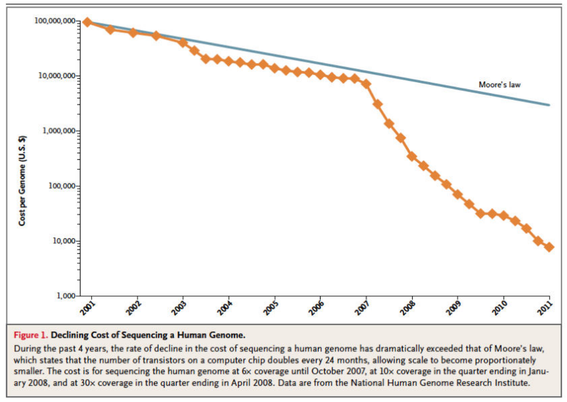


Figure 1. Declining Cost of Sequencing a Human Genome.
During the past 4 years, the rate of decline in the cost of sequencing a human genome has dramatically exceeded that of Moore's law, which states that the number of transistors on a computer chip doubles every 24 months, allowing scale to become proportionately smaller. The cost is for sequencing the human genome at 6× coverage until October 2007, at 10× coverage in the quarter ending in January 2008, and at 30× coverage in the quarter ending in April 2008. Data are from the National Human Genome Research Institute.

Cancer immunotherapy: moving beyond current vaccines

Steven A Rosenberg, James C Yang & Nicholas P Restifo

Great progress has been made in the field of tumor immunology in the past decade, but optimism about the clinical application of currently available cancer vaccine approaches is based more on surrogate endpoints than on clinical tumor regression. In our cancer vaccine trials of 440 patients, the objective response rate was low (2.6%), and comparable to the results obtained by others. We consider here results in cancer vaccine trials and highlight alternate strategies that mediate cancer regression in preclinical and clinical models.

patients who achieved clinical responses, many cancer vaccine trials have been optimistically reported because surrogate or subjective endpoints were achieved. Sensitive techniques such as tetramer or ELISpot assays have been used to demonstrate the generation *in vivo* of antitumor T cells in vaccinated patients, but the scarcity of clinical responses in these patients has made it difficult to validate any of these assays as a useful surrogate of clinical response.

Analysis of trials using standard oncologic criteria

Standard oncologic criteria for evaluating and reporting objective clinical responses to treatment are well established in oncology, and

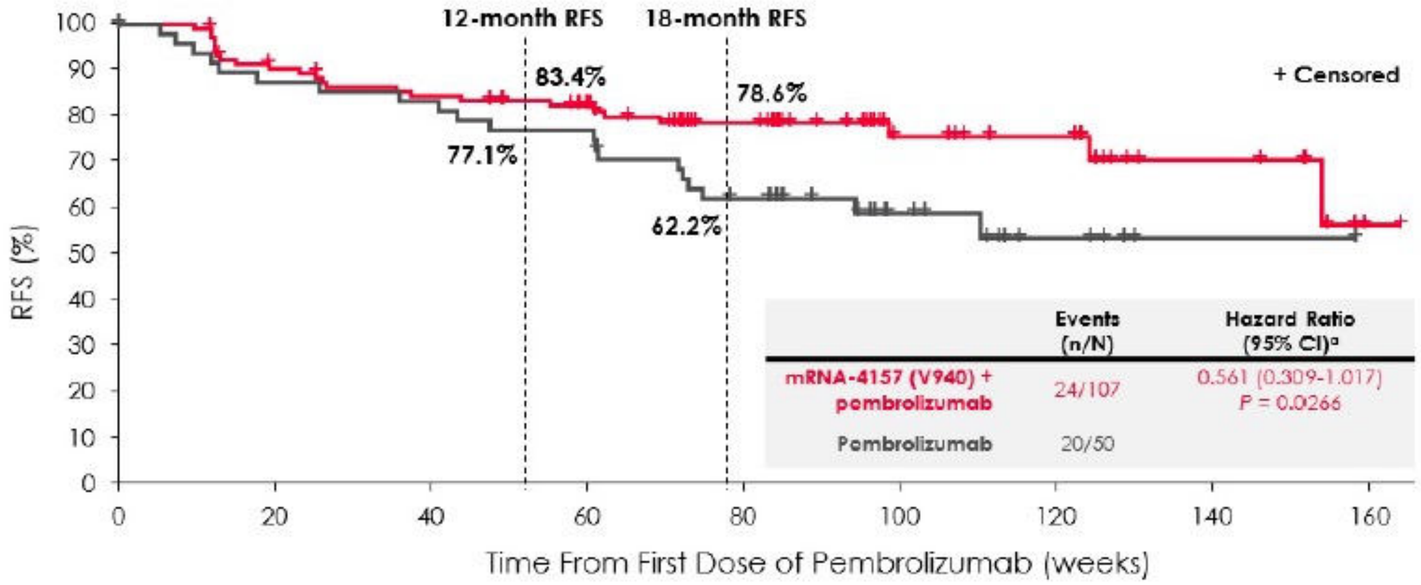
Adding a Personalized mRNA Cancer Vaccine to Immunotherapy May Prolong Recurrence-free Survival in Patients With High-risk Melanoma

Clinical benefit was independent of patients' tumor mutational burden



Number at Risk									
mRNA-4157 (V940) + Pembrolizumab	107	92	85	73	49	24	20	8	1
Pembrolizumab	50	42	40	37	28	13	6	1	0

CI, confidence interval; mRNA, messenger RNA; RFS, recurrence-free survival.
aThe hazard ratio and 95% CI for mRNA-4157 (V940) plus pembrolizumab versus pembrolizumab is estimated using a Cox proportional hazards model with treatment group as a covariate, stratified by disease stage (stages IIB or IIIC or IIID vs stage IV) used for randomization. The *P* value is based on a 1-sided log-rank test stratified by disease stage (stages IIB or IIIC or IIID vs stage IV) used for randomization.
